

**1. Intro.** Given a graph  $g$  with  $m$  edges, make data from which DLX2 should tell us all ways to label the vertices, using distinct labels in  $\{0, 1, \dots, m\}$ , so that the edges have distinct difference. (Those differences will be  $\{1, \dots, m\}$ .)

Each label could be complemented with respect to  $m$ . I avoid this by “orienting” the edge labeled  $m$ .

```
#define encode(x) ((x) < 10 ? (x) + '0' : (x) < 36 ? (x) - 10 + 'a' : (x) < 62 ? (x) - 36 + 'A' : (x) + 99)
#define maxm 156 /* based on that encoding, but I could go higher in a pinch! */
#include <stdio.h>
#include <stdlib.h>
#include "gb_graph.h"
#include "gb_save.h"
int c;
main(int argc, char *argv[])
{
    register int i, j, k, m, n;
    register Arc *a;
    register Graph *g;
    register Vertex *v;
    <Process the command line 2>;
    <Output the item-name line 3>;
    for (k = 1; k ≤ m; k++) <Output the options for edge k 4>;
}
```

**2.** <Process the command line 2> ≡

```
if (argc ≠ 2) {
    fprintf(stderr, "Usage: %s foo.gb\n", argv[0]);
    exit(-1);
}
g = restore_graph(argv[1]);
if (!g) {
    fprintf(stderr, "I couldn't reconstruct graph %s!\n", argv[1]);
    exit(-2);
}
m = g-m/2, n = g-n;
if (m ≥ maxm) {
    fprintf(stderr, "Sorry, at present I require %d!\n", maxm);
    exit(-3);
}
printf("%s\n", argv[0], argv[1]);
```

This code is used in section 1.

3. There's a primary item  $k$  for each edge label, and a primary item  $uv$  for each edge. This enforces a permutation between edges and labels.

There's a secondary item  $.v$  for each vertex; its color will be its label.

There's a secondary item  $+k$  for each vertex label; its color will be the vertex so labeled.

⟨Output the item-name line 3⟩ ≡

```

for ( $k = 1; k \leq m; k++$ ) printf ("%c␣", encode( $k$ ));
for ( $v = g\text{-vertices}; v < g\text{-vertices} + n; v++$ )
  for ( $a = v\text{-arcs}; a; a = a\text{-next}$ )
    if ( $a\text{-tip} > v$ ) printf ("%s-%s␣",  $v\text{-name}, a\text{-tip}\text{-name}$ );
printf ("|");
for ( $v = g\text{-vertices}; v < g\text{-vertices} + n; v++$ ) printf ("␣.%s",  $v\text{-name}$ );
for ( $k = 0; k \leq m; k++$ ) printf ("␣+%c", encode( $k$ ));
printf ("\n");

```

This code is used in section 1.

4. **#define** *vrt*( $v$ ) ((**int**)(( $v$ ) -  $g\text{-vertices}$ ))

⟨Output the options for edge  $k$  4⟩ ≡

```

{
  for ( $i = 0, j = k; j \leq m; i++, j++$ ) {
    for ( $v = g\text{-vertices}; v < g\text{-vertices} + n; v++$ )
      for ( $a = v\text{-arcs}; a; a = a\text{-next}$ )
        if ( $a\text{-tip} > v$ ) {
          printf ("%c␣%s-%s␣.%s:%c␣.%s:%c␣+%c:%c␣+%c:%c\n", encode( $k$ ),  $v\text{-name}, a\text{-tip}\text{-name},$ 
             $v\text{-name}, \text{encode}(i), a\text{-tip}\text{-name}, \text{encode}(j), \text{encode}(i), \text{encode}(\text{vrt}(v)), \text{encode}(j),$ 
             $\text{encode}(\text{vrt}(a\text{-tip}))$ );
          if ( $i \neq 0 \vee j \neq m$ ) /* prevent complementation symmetry */
            printf ("%c␣%s-%s␣.%s:%c␣.%s:%c␣+%c:%c␣+%c:%c\n", encode( $k$ ),  $v\text{-name}, a\text{-tip}\text{-name},$ 
               $v\text{-name}, \text{encode}(j), a\text{-tip}\text{-name}, \text{encode}(i), \text{encode}(j), \text{encode}(\text{vrt}(v)), \text{encode}(i),$ 
               $\text{encode}(\text{vrt}(a\text{-tip}))$ );
        }
      }
  }
}

```

This code is used in section 1.
